Abstract

We present a photographic identification guide and atlas to all species of bees of the Northwest Territories, Canada. So far, 109 bee species, within 18 genera, have been recorded in the Northwest Territories, Canada. It is suggested that further surveys in this vast landscape will be necessary to better understand the diversity of bee species in this region of northern Canada.

Introduction

Pollinators play an extremely important role in maintaining terrestrial ecosystems. Approximately 35% of crops are pollinator-dependent (Klein *et al.*, 2007) and most of these pollinators are bees (Kremen *et al.*, 2002; Gallai *et al.*, 2008). The classic example is the honey bee (*Apis mellifera* L.), managed worldwide for its pollination services and production of honey and wax (National Academy of Sciences, 2007). However, this species is at risk due to continued threat from diseases and other mortality factors, such as CCD (vanEnglesdorp *et al.*, 2009). Although honey bees are used for many pollination services, wild bee species are sometimes more effective in the pollination of certain crops (Buchmann and Nabhan, 1996; National Academy of Sciences, 2007). Wild bee populations play essential ecological as well as economic roles (Biesmiejer *et al.*, 2006; National Academy of Sciences, 2007), thus expanding our knowledge of these insects is of great importance.

Bees are considered keystone taxa in most terrestrial ecosystems (Sheffield *et al.*, 2003) and are also excellent indicators of the state of the environment because they have a higher extinction risk than do other organisms (Packer, 2010). Both the diversity and abundance of native bees are declining due to the intensification of agriculture and other anthropogenic impacts (Biesmiejer *et al.*, 2006; Kremen *et al.*, 2002; Steffan-Dewenter *et al.*, 2005).

The study of taxonomy, although exceedingly important, is suffering from a barrier where the number of experts is not nearly enough to identify the vast number of species. As interest in bee diversity is peaking, the ability to recognize them to species level is becoming increasingly important. There are currently over 19,700 bee species worldwide (Ascher and Pickering, 2012), however identification skills for bees are not common, especially for genera with a multitude of species. Without the ability to place names on specimens, survey work will not yield much useful information and biodiversity and pollination studies prove difficult.

Recent scientific advancements include DNA barcoding, a method increasingly used over the last several years to aid in identification of organisms. The Consortium for the Barcode of Life (CBOL) was initially launched in 2004 in Guelph, Ontario and has since been gaining recognition internationally. This method specifically uses mitochondrial DNA to obtain short and standardized genetic sequences where diversity could be used to differentiate among animal species (Ratnasingham and Heber, 2007). With the help of this technique, many problematic bee taxa could be resolved.

It is particularly crucial to increase our understanding of the bees of Canada's north, as this region is experiencing the most dramatic effects of climate change; the flora and pollinators are expected to be

impacted through processes such as phenological mismatching due to changed conditions (Lovejoy and Hannah, 2005). Furthermore, being particularly temperature dependent (even for insects), bee populations and distributions are expected to respond rapidly to a warming climate.

Methods

We created photographs using museum specimens and provided photographic dichotomous keys to genus and species. All characters used in the key are illustrated. Images were taken using a Visionary Digital BK Plus imaging system with a Canon EOS 40D digital SLR camera and processed with Adobe Photoshop. The identification keys were generated by referring to previously written keys and modifying them specifically for the bee species of the NWT. Many keys were updated and, for this, we examined an array of specimens to incorporate them into the keys. The keys referenced include Mitchell (1960), Packer et al. (2007), Sheffield et al. (2011), Rightmyer et al. (2010), Gibbs (2010), Stephen (1954), Williams (personal communication).

The resources we provide allow for species level identification with the aid of images for a user-friendly interface. This makes it possible for the key to be usable by anyone with a microscope and a computer. These data will help to monitor bees and contribute to current knowledge on the status of these species.

Location data (Appendix C) were mapped using GIS ArcMap 10.1 and were supplied by Laurence Packer, Molly Rightmyer, Terry Griswold, Nick de Silva, Jason Gibbs, Paul Williams, Anne Gunn, Syd Cannings, and Discoverlife.org. Additional bumble bee location data were obtained from Leif Richardson (Williams et al. 2014). We also retrieved many records from these museum collections: Packer Collection at York University (Toronto, ON), Canadian National Collection (Ottawa, ON), Lyman Entomological and Research Laboratory at McGill University (Montreal, QC).

Results

One photographic key to the genera of bees for the NWT is presented in Appendix A. The genera key is modified from Packer et al. (2007). The only bee species alien to NWT's ecosystems but part of a growing apiary home industry, *Apis mellifera*, is also keyed in Appendix A. The genera key leads to a set of keys to bee species (Appendix B) organized based on classification by Michener (2007) (Table 1).

Table 1. List of bee genera in the NWT and key details

Genera	Key details and notes	Appendix
Colletidae – Plasterer bees and relatives		
<i>Colletes</i>	Five (5) species of plasterer bees are known to occur in the NWT. <i>Colletes</i> are solitary bees, individually constructing a nest with provisioned cells for their eggs, but then leave and do not feed their offspring. They are ground nesting bees. They are known as plasterer bees due to their use of a cellophane-like secretion for lining nests. A defining characteristic of this genus is the s-shaped second recurrent	B1

	vein on the forewing.	
<i>Hylaeus</i>	Four (4) species of masked bees are known to occur in the NWT. They have yellow or cream markings on their face and body. <i>Hylaeus</i> bees are cavity nesters, usually constructing nests in dead plant twigs or stems, lining the individual provisions with a cellophane-like secretion. Females do not have pollen-collecting hairs like most other bees because they carry pollen internally in their crop.	B1
Andrenidae – Andrenid bees		
<i>Andrena</i>	Seventeen (17) species of miner bees are known to occur in the NWT. An additional species <i>A. nigrihirta</i> , is not included in the key, was collected only once (Map 19: Yellowknife 1949), and needs verification. They are ground nesting bees and known as mining bees due to their habitat of digging soil and sand for constructing underground nests. A defining characteristic of this genus is the facial foveae, which are longitudinal depressions (varying in length) on the face between the compound eye and the antenna. The facial foveae are usually covered in dense, short, velvety hairs, but are more prominent in females than males.	B2
<i>Panurginus</i>	One species, <i>P. ineptus</i> , may occur in the NWT. Specimens need verification.	A
Halictidae – Halictic bees		
<i>Dufourea</i>	Only one species of Dufourea sweat bee is known to occur in the NWT. <i>Dufourea fimbriata</i> is oligolectic, a floral specialist, on <i>Potentilla</i> . It is a solitary bee nesting in burrows below ground. The defining characteristics are the antennae arising low on the face and the forewing with 2 submarginal cells. They are relatively uncommon in Canada. Refer to the key in Dumesht and Sheffield (2012) for <i>Dufourea</i> in all of Canada.	B3
<i>Halictus</i>	Three (3) species of sweat bees are known to occur in the NWT. Species from subgenera <i>Seladonia</i> (metallic green) and <i>Protohalictus</i> (not metallic) and are present in the NWT. These sweat bees are ground nesters and can be eusocial or solitary bees. Sometimes the same species can exhibit different behaviour depending on climate (Soucy and Danforth 2001). A defining characteristic of this genus is the apical hair bands on the abdominal segments (<i>Lasioglossum</i> have basal hair bands).	B3
<i>Lasioglossum</i>	Twelve (12) species of veined sweat bees are known to occur in the NWT. Species from subgenera <i>Lasioglossum</i> (strong-veined), as well as	B3

Evylaeus (weak-veined) and *Dialictus* (metallic) are present in the NWT. Nine species are included in the key. Some species are missing due to recent taxonomic revisions: *L. laevissimum*, *L. novascotiae*, and *L. seilleian* (new: Gibb et al. 2013). *L. rufitarse* in North America, including in the NWT, are now recognized as *L. inconditum* (Gibb et al. 2013). These bees are ground nesting and can be eusocial or primitively eusocial. Members of this genus are called sweat bees as they are known to lick sweat off of mammals (including humans). A defining characteristic of this genus is the basal hair bands on the abdominal segments (*Halictus* have apical hair bands).

<i>Sphecodes</i>	Three (3) species of parasitic Halictic bees are known to occur in the NWT. Due to incomplete taxonomic knowledge of this genus in North America, the key is tentative. More species could be found in the NWT. All species are cleptoparasitic. Females do not have pollen collecting hairs as they use the resources of other bees which they parasitize. A defining characteristic is their coarse punctures and red abdomen, whereas the rest of the body is black.	B3
------------------	---	----

Megachilidae – Leafcutter bees and relatives

<i>Hoplitis</i>	Three (3) species of Hoplitis mason bees are known to occur in the NWT. An additional species, <i>H. fulgida</i> , is not included in the key and may be present. These solitary bees build nests in the ground.	B4
<i>Osmia</i>	Thirteen (13) species of mason bees are known to occur in the NWT. These solitary bees build mud nests in burrows, cavities or in old wood.	B4
<i>Anthidium</i>	Two (2) species of potter bees are known to occur in the NWT. An additional species, <i>A. palliventre</i> , is not included in the key, was collected once (map 44), and needs verification. These solitary bees build cells in their nest with resin, plant fragments, mud or a mix of material in burrows, cavities or in old wood.	B4
<i>Stelis</i>	Three (3) species of parasitic mason bees are known to occur in the NWT. An additional un-described but distinct species is provided in the key. Due to incomplete taxonomic knowledge of this genus in North America, the key is tentative. More species could be found in the NWT. All species are cleptoparasitic.	B4
<i>Coelioxys</i>	Five (5) species of cuckoo leafcutter bees are known to occur in the NWT. All species are cleptoparasitic.	B4
<i>Megachile</i>	Nine (9) species of leafcutter bees are known to occur in the NWT.	B4

Species from subgenera *Sayapis*, *Xanthosarus*, *Megachile* are present in the NWT. An additional species *M. centumcularis*, not included in the key, was collected only once and needs verification. These solitary bees build nest cells with plant fragments in burrows or cavities.

Apidae – Honey bees and relatives

<i>Epeolus</i>	Only one species of <i>Epeolus</i> cuckoo bee, <i>E. minimus</i> , is known to occur in the NWT. All species are cleptoparasitic.	B5
<i>Nomada</i>	Six (6) species of nomad bees are known to occur in the NWT. Due to incomplete taxonomic knowledge of this genus in North America, the key is tentative. Many more species could be found in the fauna of the NWT. All species are cleptoparasitic.	B5
<i>Anthophora</i>	Two (2) species of flower bees are known to occur in the NWT. These solitary bees build nest in the soil.	B5
<i>Bombus</i>	Twenty-one (21) species of bumble bees are known to occur in the NWT. Species from subgenera <i>Bombus</i> , <i>Pyrobombus</i> , <i>Alpinbombus</i> , <i>Subterraneobombus</i> , and <i>Psithyrus</i> are present in the NWT. <i>Psithyrus</i> are cleptoparasitic. All other subgenera are eusocial, forming small to somewhat large colonies that in our region mostly survive a single season. Bumble bee queens hibernate. <i>Alpinbombus</i> prefer cold regions.	B5
<i>Apis</i>	Only one species, western honey bee (<i>A. mellifera</i>), is known to have been introduced to the NWT. They are advanced eusocial species, forming multi-year cooperative hives with different reproductive and worker castes. They are notorious for their honey and wax production. Colonies can survive our harsh winters only if shelter is provided.	A and B5

Discussion

Currently, there are over 800 known bee species in Canada and 109 of these, belonging to 18 genera, have been recorded for the NWT. This project has yielded working keys to all genera and species currently known from the NWT. The key couplets are illustrated to facilitate identification; this will allow both expert and novice users to put names on bee species. Having the tools to identify species will allow for further studies on bees in Northern Canada. Identification guides are important not only for melittologists and other entomologists, but for all other researchers and naturalists interested in assessing and monitoring fauna. The map distributions of bee species currently found in this region will also help determine where further sampling should take place. Prior to this study, a guide to the bee species of NWT was unavailable.

Monitoring the flora and fauna of Northern Canada is extremely important for assessing their status and conservation requirements. This project was intended towards providing a better understanding of the distribution and conservation status of bees in the NWT through establishing a guide to identify bee species in the region and by compiling a location database of all species recorded from this region. Studying the bee diversity in the NWT is especially important as the Arctic is among the ecosystems most prone to the effects of climate change. Bees act keystone organisms in most terrestrial ecosystems due to their role as pollinators. By providing this service, bees benefit many other organisms in their ecosystem. Furthermore, they have great potential for environmental monitoring and could be used to assess ecosystem health.

There is a lack of data on bees (and other insects) from Northern Canada, and many bee species remain unrecorded, and the true distribution of many may be much broader. Several species have only recently been recorded as presented here. It is essential to continue surveying more land, in more remote areas of the NWT, as this will give us a better understanding of the bee communities which occur here. There are many species recorded from adjacent Yukon and provinces to the south that have not yet been found in the NWT. Extensive sampling in this region will probably yield interesting species records and possibly some generic additions. DNA barcoding is proving very important in species identification. A growing database acts as a storage library of reference DNA sequences for known species. These data could be accessed and compared to problematic or otherwise difficult to determine species. With the help of DNA barcoding, advancements have been made on finding new species, raising sub-species to species, synonymizing species, and associating sexes of one species previously described as different species. With the help of DNA barcoding, (recently collected) bee specimens could be processed and compared to others in the database in order to help with identification. This will also contribute to the ongoing efforts of DNA barcoding and increase the number of Arctic/circumpolar records currently in the database.

There still remain unresolved taxonomic problems for many groups of bees. Identification keys are unavailable for some genera, while others have been very well studied. For example, *Nomada*, *Sphecodes*, and *Stelis* are cleptoparasitic genera for which identification keys covering all species are not yet available for all of North America. Some studies have been done elsewhere in North America; however, many gaps remain in our knowledge of these groups. In such cases, specimens must be compared to the available species descriptions, some of which were written many decades ago and may not be useful. In addition, several genera include species which are very difficult to differentiate based on morphological characteristics. These require taxonomic experts to review all known species, and perhaps new ones, to come up with a means of identifying them. Another issue is variation within species. An example of this is the colour variation in *Bombus*. Species of bumble bees exhibit different colour patterns, even within the same species. This makes it difficult to identify these species, unless all variants are recorded and accounted for. For all of the above reasons, having illustrations of the characters used in keys is an extremely valuable tool to help during identification. Much more work is necessary to produce a working key for all Canadian bees, but the present keys for the NWT could be looked at as one step towards that goal.

Acknowledgments

We would like to thank Laurence Packer, Jason Gibbs, Nick de Silva, Molly Rightmyer, Terry Griswold, and Paul Williams for taxonomic assistance on some bee groups.

The photographic system was purchased with funds from the Canadian Foundation for Innovation and the Ontario Research Fund through Canadensys to Laurence Packer, York University.

We thank Laurence Packer, Molly Rightmyer, Terry Griswold, Nick de Silva, Jason Gibbs, Paul Williams, Anne Gunn, and Syd Cannings for collecting bees and providing location data. We thank these institutions for allowing use of label records: Packer Collection at York University, Canadian National Collection, Lyman Entomological and Research Laboratory at McGill University. Layout was done by Chloe Smith, GIS work by Bonnie Fournier, map illustrations by Suzanne Carrière, Environment and Natural Resources, Government of the NWT.

The project was partly funded by the Government of the NWT, Department of Environment and Natural Resources, as part of a project under the NWT Conservation Data Centre, NatureServe Canada and the NWT General Status Ranking Program. Special thanks to all for making this project possible.

Panurginus

Species of this genus have not yet been recorded for the Northwest Territories, but have been recorded in Yukon; therefore, it is likely that they occur in the adjacent Northwest Territories. In anticipation of these occurrences, these genera are included here.

B3: Key to bee species in the Halictidae family

Dufourea

Dufourea is a relatively uncommon genus of bees in Canada. This is the only Canadian genus in the family Halictidae with only two submarginal cells on the forewing. This species is small and black with pale whitish hairs. The head is wider than long and the antennae arise low on the face. The clypeus is therefore quite short relative to that of other bee genera.

Dufourea fimbriata

(App. C, Map 27)

Apis

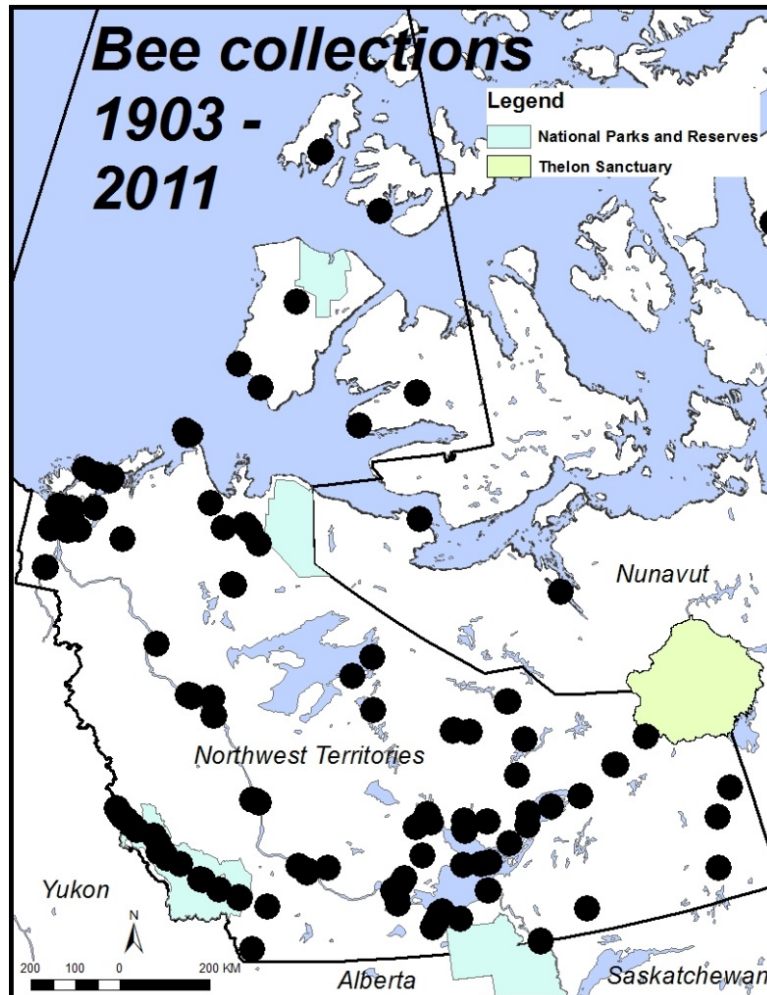

Apis mellifera, commonly known as the honey bee, is an introduced species. It is also the only species that lives in a colony all year long. This species, along with *Bombus* (Bumblebees) could be distinguished by the corbicula (pollen basket) on their hind legs, where they store pollen (females only). Other bee species usually transport pollen on their hind legs or lower abdomen (sterna) where the hairs are dense.....

Apis mellifera
